(54) Title: PROMOTER FOR THE RECEPTOR TYROSINE KINASE, TIE

### (57) Abstract

The present application discloses promoter sequences for *Tie*, an endothelial cell receptor tyrosine kinase and their use in therapy and diagnosis as well as production of proteins in blood and tissues.

**PROMOTER FOR THE RECEPTOR TYROSINE KINASE, TIE**

**FIELD OF THE INVENTION**

The present invention relates generally to receptor tyrosine kinases and promoters thereof.

5 **BACKGROUND OF THE INVENTION**

The circulatory system is the first organ system to differentiate in the developing embryo. Kaufman, *The Atlas of Mouse Development*, Academic Press, (1992). Embryonic and yolk sac vascular systems take form in an 8.5 day p.c. mouse embryo and a day later the heart beats regularly, circulating primitive blood cells, nutrients, and metabolic waste products. Endothelial cells covering blood vessels provide a barrier between blood and other tissues of the embryo. When organs differentiate and begin to perform their specific functions, the phenotypic heterogeneity of endothelial cells increases. Fenestrated vessels, nonfenestrated vessels with tight junctions and sinusoidal vessels are found, for example, in the kidney, brain, and liver, respectively. In addition, endothelial cells perform specific functions in differentiated tissue. For example, such cells take part in several biochemical and physiological events such as blood cell trafficking, blood clotting, hemostasis, ovulation, wound healing, atherosclerosis, and angiogenesis associated with tumor metastasis.

At least five receptor tyrosine kinase genes are expressed in endothelial cells. Of these, the protein products of the FLT1, KDR/FLK-1, and FLT4 genes belong to receptor tyrosine kinase subclass III; whereas Tie and its close relative Tek

- 2 -

(Tie-2) form a novel subclass of their own (Terman, et al., *Oncogene*, 6: 1677-1683, 1991, Terman, et al., *Biochem. Biophys. Res. Comm.*, 187: 1579-1586, 1992, Aprelikova, et al., *Cancer Res.*, 52: 746-748, 1992, De Vries, et al., *Science*, 255: 989-991, 1992, Pajusola, et al., *Cancer Res.*, 52: 5738-5742, 1992, Sarzani, et al., *Biochem. Biophys. Res. Comm.*, 186: 796-714, 1992, Galland, et al., *Oncogene*, 8: 1233-1240, 1993, Millauer, et al., *Cell*, 72: 10 835-846, 1993, Oelrichs, et al., *Oncogene*, 8: 11-18, 1993, Schnurch and Risau, *Development*, 119: 957-968, 1993). Both human and mouse Tie cDNAs have been cloned (Partanen, et al., *Mol. Cel. Biol.*, 12: 1698-1707, 1992, Korhonen, et al., *Blood*, 80: 15 2548-2555, 1992, Korhonen, et al., *Oncogene*, 8: 395-403, 1994, Iwama, et al., *Biochem. Biophys. Res. Comm.*, 195: 301-309, 1993, Sato, et al., *Proc. Natl. Acad. Sci. USA.*, 90: 9355-9358, 1993). Tie and homologous genes have been isolated from bovine and 20 rat sources (Maisonpierre, et al., *Oncogene*, 8: 1631-1637, 1993, Sato, et al., *Proc. Natl. Acad. Sci. USA.*, 90: 9355-9358, 1993). Genomic clones for mouse Tie and both mouse and human Tie promoter regions have been cloned and characterized.

25 The 4.4 kb Tie-encoding mRNA encodes a 125 kDa transmembrane protein which is N-glycosylated. In its extracellular domain Tie contains two immunoglobulin-like loops and three epidermal growth factor and fibronectin type III homology regions, 30 which are followed by trans- and juxtamembrane domains connected to a tyrosine kinase domain which is split by a short kinase insert sequence and a carboxyl terminal tail (Partanen, et al., *Mol. Cel. Biol.*, 12: 1698-1707, 1992, Korhonen, et al., *Oncogene*, 8: 395-403, 1994, Sato, et al., *Proc.*

- 3 -

Natl. Acad. Sci. USA., 90: 9355-9358, 1993). Both Tie and TEK have been localized to mouse chromosome 4 at a distance of 12.2 cm from each other. Such receptors are uniformly expressed in endothelial 5 cells of various blood vessels during embryonic development, although the expression of Tek mRNA appears to begin 0.5 days earlier than the expression of Tie. In adult mice, the expression of Tie mRNA persists in vessels of the lung whereas in 10 the heart and brain it appears to decrease.

Korhonen, et al., *Oncogene*, 8: 395-403, (1994). Production of Tie mRNA is enhanced during ovulation and wound healing and in human glioblastomas (Korhonen, et al., *Blood*, 80: 2548-2555, 1992).

15 Endothelial cells play a key role in gene therapy directed to diseases involving endothelial cells and blood vessels, such as establishment of neovascularization or inhibition of angiogenesis, and control of inflammatory trafficking of 20 leukocytes. One approach to the treatment of vascular disease is to express genes at specific sites in the circulation that might ameliorate the disease *in situ*. Because endothelial cells are found at diseased sites, they represent logical 25 carriers to convey therapeutic agents that might include anticoagulant, vasodilator, angiogenic or growth factors. Accordingly, the genetic modification of endothelial cells represents a therapeutic approach to the treatment of many 30 vascular disorders, including hypertension, atherosclerosis and restenosis. For example, endothelial cells expressing growth inhibitory proteins could be introduced via catheter to the angioplasty site to prevent local intimal 35 hyperplasia and clinical restenosis. The luminal

- 4 -

surface of vascular grafts could also be lined with genetically modified endothelial cells producing therapeutic proteins which prevent thrombosis or promote repopulation (Nabel, et al., J. Am. Coll. Cardiol., 17, 189B-194B, 1991).

5

Endothelial cells lining blood vessels are easily transfected with methods using liposomes, adenovirus vectors and retroviral vectors (Nabel, et al., J. Am. Coll. Cardiol. 17: 189B-94B).

10

Endothelial cells are also in direct contact with blood and are therefore optimal sources for production and secretion of desired proteins or peptides into the blood stream. For example, the Factor VIII gene may be introduced into endothelial cells under an endothelial cell- specific promoter, resulting in correction of hemophilia if the protein were expressed in sufficient quantity. On the other hand, endothelial cells are also useful for delivery of peptides or proteins expressed in them into tissues. In this regard, a selective expression of a particular gene regulatory element in endothelial cells of the microvasculature (capillaries) is extremely useful, given that most of the cell surface area facing the vascular lumen consists of

15

microvascular endothelial cells.

20

Control elements of the endothelial cell specific promoters may be further subdivided and dissected into functional elements and units according to methods standard in the art. The Tie protein is expressed in certain endothelial cells and about 0.9% of human bone marrow cells.

25

Therefore, it is likely that the Tie promoter is active also in some hematopoietic cells. However, expression of the Tie promoter in hematopoietic cells may be controlled by elements which are

- 5 -

distinguishable from endothelial-cell-specific elements and may be dissected away while retaining the endothelial cell specificity of the promoter.

The present invention provides a novel promoter associated with the gene encoding the Tie receptor tyrosine kinase for use in therapeutic and diagnostic procedures. In addition, the promoter may prove useful in the production of desired proteins to the blood or tissues of animals.

10 SUMMARY OF THE INVENTION

The present invention generally relates to promoter sequences for the receptor tyrosine kinase, Tie. In a preferred embodiment of the invention, a mouse Tie promoter is provided comprising the sequence shown in SEQ ID NO:1. Also in a preferred embodiment, a human Tie promoter is provided comprising the sequence shown in SEQ ID NO:2. A promoter according to the invention drives the expression of endothelial cell receptor tyrosine kinases, and in particular, the receptor tyrosine kinase, Tie.

A vector according to the present invention may be any vector suitable for incorporating a promoter according to the invention and may preferably be the 5.OhpronSDKLacZ vector deposited on September 20, 1994 with the American Type Culture Collection, 12301 Parklawn Drive, Rockville, MD 20852, as Accession Number 75892.

Host cells according to the invention may be any host cell capable of housing the promoter or a vector containing the promoter according to the invention. Examples of host cells according to the invention are LEII endothelial cells.

- 6 -

Other advantages and uses of the invention will be apparent upon consideration of the following Detailed Description thereof.

#### DESCRIPTION OF THE DRAWINGS

5 Figure 1 is a schematic diagram of the mouse Tie gene and promoter.

Figure 7E shows expression of the Tie promoter in liver tissue of an 8-week-old mouse.

Figure 7F shows expression of the Tie promoter in brain tissue of an 8-week-old mouse.

15 **DETAILED DESCRIPTION OF THE INVENTION**

The present invention provides promoter sequences capable of directing the expression of recombinant DNA sequences in endothelial cells. In particular, the invention provides promoter sequences which direct expression of the beta-galactosidase reporter gene in endothelial cells of mouse tissues. Promoters for production of proteins and peptides which act as anticoagulants, vasodilator inhibitors of thrombosis or restenosis 25 into endothelial cells, blood and tissues.

Promoters according to the present invention are useful for directing expression of proteins and peptides for human gene therapy, antigens and markers useful for endothelial cell tagging, and 30 antisense RNA constructs for use in endothelial cells *in vivo* and *in vitro*. Promoters, vectors, and host cells according to the invention are also useful in gene therapy for promoting expression of various growth factors or receptors or their

- 8 -

domains. Moreover, analogs of promoters according to the invention are useful for inhibiting undesired endothelial cell proliferation as, for example, the inhibition of angiogenesis during tumor formation.

5

#### EXAMPLE I

##### Cloning and characterization of the genomic Tie DNAs.

###### A. Mouse Genomic Tie

In order to characterize the genomic organization of the mouse Tie gene, approximately 3 x 10<sup>6</sup> plaques were screened. The plaques were obtained from a genomic library made from DNA of adult SV129 mouse liver cells (Clontech) using as a probe a mouse 1C1D cDNA fragment (Korhonen, et al., Blood., 80:2548-2555, 1992) encoding the epidermal growth factor homology domains [GCVKDCPGCLHGGVCHDHGCVCPPGFTGTRCEQACREGRFGQSCQEQQCPG TAGCRGLTFCLPDPYGCSCGSGWRGSQCQEACAPDHFGADCRLQCQCQNGGT CDRFSGCVCPGWHGVHCEKSDRIPQIL: SEQ ID NO:3] Three separate clones, SV1, SV2, and mTie were obtained thereby and each was subcloned into pGEM 3Zf(+) (Promega) and characterized by partial dideoxy chain termination sequencing and restriction enzyme analysis. A schematic structure of the mouse Tie gene and its promoter is shown in Figure 1. In that Figure, the positions of introns are indicated by arrows and their lengths are indicated. Restriction mapping, PCR, and nucleotide sequence analysis showed that the Tie gene spans approximately 19 kb of genomic DNA. Tie is encoded by 23 exons. The distinct structural domains of the extracellular portion are encoded by either one exon each, comprising the first immunoglobulin-like loop, epidermal growth factor homology domains 1-3 and

SUBSTITUTE SHEET (RULE 26)

- 9 -

fibronectin-like domains 2 and 3, or by two exons comprising the second immunoglobulin-like loop and first fibronectin-like domain. The transmembrane region is encoded by a distinct exon; whereas the 5 tyrosine kinase domain containing the kinase insert is encoded by eight exons of which the first encodes the juxtamembrane region. The lengths of the introns vary from 80 bp to 2.6 kb.

#### B. Human Genomic Tie

10 Three human Tie clones were isolated from a human placental cDNA library in the EMBL-3 vector system (Clontech) as shown in Partanen, et al., *Mol. Cell. Biol.*, 12: 1698-1707 (1992); incorporated by reference herein. To obtain the human Tie clones, a 15 PCR fragment encoding the Tie signal sequence was amplified from human Tie cDNA using the primers, 5'-CCCACATGAGAAGCC-3' (SEQ ID NO: 4) and 5'-TGAGATCTTGGAGTATGGCTGGCGGGTGCC-3' (SEQ ID NO: 5), and used to probe the aforementioned library. 20 The resulting positive clone containing the longest insert was plaque-purified and an approximately 7 kb SacI fragment was subcloned in pGEM 3Zf(+) and characterized. The resulting human Tie promoter sequence is shown in Figure 2. In that Figure, 25 transcription initiation sites are marked with an asterisk (See primer extension and RNase protection experiments below). Restriction endonuclease cleavage sites discussed herein are marked in bold. A comparison of the genomic DNA sequences 30 of mouse and human Tie promoters is also shown in Figure 2. In that Figure, the mouse sequence extends from the 3' end of the first exon to the *Afl*III site which is approximately 772 bp upstream

- 10 -

from the ATG codon. A CA repeat found only in the mouse sequence is highlighted in bold in Figure 2.

EXAMPLE II

5 Determination of The Transcription Initiation Site  
in The Human Tie Gene

For primer extension analysis of Tie-encoding nucleic acids, primer was labelled according to the manufacturer's instruction (Promega, USA). An aliquot of 10 pmol primer was 10 then incubated with 10 x forward exchange buffer (Promega), 10 mCi/ml [ $\gamma$ -32p]-ATP, and 10U T4 polynucleotide kinase at 37°C for 1 hour. The kinase was then inactivated by heating at 90°C for 2 minutes and the labelled primer was ethanol 15 precipitated.

Poly (A+) RNA (20 mg) and  $5 \times 10^5$  cpm labelled primer were then annealed in hybridization buffer (40 mM PIPES pH 6.4, 1mM EDTA pH 8.0, 0.4 M NaCl and 80% formamide) by heating at 95°C for 12 20 minutes. Samples were then cooled slowly and ethanol precipitated. The resulting dried annealing mixture was suspended in primer extension buffer (50 mM Tris- HCl, 50 mM KCl, 10 mM MgCl<sub>2</sub>, 10 mM DTT, 2 mM each of deoxy ATP, deoxy CTP, deoxy GTP, and deoxy 25 TTP, 0.5 mM spermidine, pH 8.3, at 42°C) and 20 U RNAsin and 40 U AMV reverse transcriptase were added. After 2 hours of incubation, template RNA was digested by addition of 20 mg/ml RNase A in 100 mM 30 NaCl, 10 mM Tris-HCl, 1 mM EDTA, pH 7.4, 37°C for 15 minutes. The resulting mixture was phenol extracted and ethanol precipitated. The pellet was then resuspended in loading dye (98% formamide, 10 mM EDTA, 0.1% xylene cyanol, 1% bromophenol blue) and loaded onto a 9% polyacrylamide/7M urea gel. After

- 11 -

electrophoresis, the dried gels were exposed to x-ray film for 2 days.

RNAase protection was accomplished using mouse RNA antisense probes of 291 bp and 239 bp generated from linearized plasmids containing the 754 bp *Af*III - *Bam*HI and 1.1 kb *Hind*III - *Ap*I mouse *Tie* promoter DNA inserts. The human RNA probe of 568 bp was generated from linearized pGEM 3zf(+) plasmid (Promega, USA) containing an *Acc*I-*Alw*NI human *Tie* promoter DNA insert. The template for the other human 266 bp RNA probe was generated by PCR amplification from the *Acc*I-*Alw*NI plasmid. M13 Forward and *Tie* 2168 primers (marked in Figure 2) were used for amplification. The probes were labeled using T7 polymerase and [ $\alpha$ -32P]-UTP. 10 $\mu$ g of poly A(+) RNA was incubated with labelled probe at 50°C overnight. Unhybridized RNA was digested with RNase A (10 U/ml) and T1 (1 g/ml) at 37°C, pH 7.5 for 1 hour. The RNases were inactivated by proteinase K digestion at 37°C for 15 minutes and the samples were analyzed in 8% sequencing gels.

The primer extension and RNase protection products terminated at positions 101 bp and 116 bp upstream from ATG codon, in mouse and human *Tie* promoters, respectively (see asterisks in Figure 2). Yeast tRNA or NIH 3T3 RNA did not show any specific bands. Results are shown in Figure 2, wherein the sequences of primers referred to above are underlined.

30

### EXAMPLE III

Construction of plasmids  
*Tie* promoter/luciferase gene constructs  
were generated by subcloning the 5' flanking 735 bp

- 12 -

genomic *Af*III-*Apa*I fragment located upstream of the *Apa*I restriction site in the first exon to the promoterless basic pGL2 vector (Stratagene) as described by deWet, et al., *Mol. Cell. Biol.*, 7: 5 725-737 (1987), incorporated by reference herein, resulting in plasmid 0.73mpromGL2.

For experiments in transgenic mice, the 735 bp *Af*III-*Apa*I promoter fragment (shown in Figure 2) was blunt-end ligated into a blunted, unique 10 *Hind*III site in the *SDK-LacZ* Bluescript vector (Stratagene), as described in Logan, et al., *Development*, 117: 905-916 (1993), incorporated by reference herein, resulting in vector 0.73mpromSDK-*LacZ*. Similarly the 5 kb *Alw*NI fragment of the 15 human *Tie* promoter shown in Figure 2 was blunt-end ligated into that same vector, resulting in plasmid 5.0hTIEpromSDK-*LacZ* and deposited with the American Type Culture Collection, 12301 Parklawn Drive, Rockville, MD 20852, as Accession Number 75893

20

#### EXAMPLE IV

DNA transfection and preparation of cell lysates  
15 ug of the 0.73mpromGL2 plasmid  
described above was transfected into either LE II  
25 mouse lung endothelial cells which are described in Schrieber, et al., *Proc. Natl. Acad. Sci. (USA)*, 82: 6138-6142 (1985), incorporated by reference herein, or MK-2 cells described by Weissman, et al., *Cell*, 32: 599-606 (1983), incorporated by reference  
30 herein. Transfection was accomplished using the modified calcium phosphate mediated transfection method reported in Sambrook, et al. (eds.), *Molecular Cloning: A Laboratory Manual* (1989) incorporated by reference herein. The DNAs were

- 13 -

mixed with 0.25 M CaCl<sub>2</sub> and an equal volume of 50 mM N,N-bis(2-hydroxyethyl)-2-aminoethane sulfonic acid-buffered saline. The mixture was incubated for 15 minutes at room temperature and then added 5 dropwise on growing cell monolayers.

The resulting cultures were incubated for 12 hours, after which 5% glycerol in PBS (phosphate buffered saline) was added for 30 seconds and washed off with two changes of PBS. Fresh medium was then 10 added. After further incubation for 24 hours, the cells were lysed in 0.5 ml lysis buffer (25 mM Tris-PO<sub>4</sub>, 2 mM dithiothreitol (DTT), 2 mM 1,2-diamino-cyclohexane, N,N,N',N'-tetracetic acid, 15 10% glycerol, 1% Triton X-100, pH 7.8). The resulting lysates were centrifuged and the supernatants were collected and stored at 70°C until further assayed. Normalization of luciferase values relative to transfection efficiency was achieved by cotransfection of a CMV-b-gal vector described in 20 MacGregor and Caskey, Nucl. Acids. Res., 17: 2365 (1989), incorporated by reference herein.

Assays for  $\beta$ -galactosidase and luciferase were conducted on transfected cells. For the  $\beta$ -galactosidase assay, 30 ml of the cell lysate 25 described above was incubated in 33 ml of o-nitrophenyl- $\beta$ -D-galactopyranoside (4 mg/ml) dissolved in 100 ml 0.1 M sodium phosphate, pH 7.5 for 30 minutes at 37°C. Optical density was measured at 414 nm.

30 Luciferase assays were performed using a FlyLight monitoring Kit (102-100, BioTools, Finland) according to the manufacturer's protocol. Briefly, 20 ml of cell lysate was incubated in 100 ml reaction mixture and a Bio-Orbit 1253 luminometer 35 was used to determine light intensity.

- 14 -

The activity of the Tie promoter in cultured cells was measured using Tie promoter-luciferase constructs described above. The Tie promoter-luciferase constructs were transfected 5 into either LEII endothelial cells or into MK-2 epithelial cells. Promoter activity was determined as the ratio of luciferase to  $\beta$ -galactosidase activity. Those activities were compared to the promoter activity of the positive control vector, 10 RSV-luc (ATCC).

Activity of the 0.73mpromGL2 plasmid (735) relative to CMV- $\beta$ -gal, used as a constitutively expressed cotransfected control promoter, is shown 15 in Figure 3, along with values for the highly expressed RSV-luc promoter. A 460 bp mouse Tie promoter fragment was used in reverse orientation as a negative control (reverse). As shown in figure 3, the Tie promoter was highly active in LEII cells but not in the epithelial cells, MK-2. Those results 20 indicate that the isolated Tie promoter is specific for vascular endothelial cells and efficiently promotes the expression of the reporter in those cells in comparison to the control.

#### EXAMPLE V

##### 25 Production of transgenic mice

The Tie-containing transgene was separated from the vector sequence by digestion with SalI, purified by electrophoresis through an agarose gel, and recovered by absorption on glass beads (Gene 30 Clean II, Bio 101 Inc., La Jolla, CA) according to the manufacturer's instructions. Transgenic mice were produced by the standard microinjection technique reported in Hogan et al., Manipulating the

- 15 -

mouse embryo (Cold Spring Harbor, 1986), incorporated herein by reference. Zygotes for microinjections were obtained from superovulated (BALB/c X DBA/2)F1 hybrid female mice (CD2F1) mated 5 with CD2F1 males. Alternatively, eggs used for injection were from randomly bred superovulated CD1 females. After microinjection, zygotes were transferred at the one or two cell stage into oviducts of pseudopregnant foster mothers (CD2F1 10 mice). Tail samples were taken from mouse pups at three weeks of age and DNA was isolated from the samples by the salt precipitation method of Miller, et al., *Nucl. Acids. Res.*, 16: 1215 (1988), incorporated by reference herein. The polymerase 15 chain reaction was used to confirm expression of the transgene using the mouse promoter-specific primer, 5'-CTATTGAGAAGGTTGGAGG3-[SEQ ID NO:6], the lacZ vector primer, 5'-GCTCTAGAACTAGTGGATC-[SEQ ID NO:7]; the human promoter-specific primer, 20 5'-GAGACAGGGATGGAAAAA-3' [SEQ ID NO:8]; and the lacZ vector primer, 5'-GAAGATCGCACTCCAGCCAG-3' [SEQ ID NO: 9] using a reaction mixture comprising 200 ng DNA (Tail), 10x buffer (2mM MgCl<sub>2</sub>), 250 nM Primer 2040, 250 nM Primer 1986, 0.2 mM dNTP Mixture, 0.02 25 U Dynazyme(Finnzymes, Finland), and 50 ml of distilled water, plus 50 ml mineral oil (M-3516; Sigma, USA). The PCR Program consisted of a hot start at 96°C, 2 minutes, with cycling as follows: 96°C 1 minutes, 50°C 2 minutes, 72°C 3 minutes, for 30 34 Cycles, with the last step delayed 10 minutes.

#### EXAMPLE VI

##### Analysis of Tie-containing Tissue

Whole mouse embryos were obtained and stained for  $\beta$ -galactosidase activity. Tissue was

- 16 -

transferred into 4% paraformaldehyde in PBS (pH 7.4) and incubated at 4°C for 20 minutes with gentle agitation. Tissue was then washed with PBS and incubated in fresh X-Gal reaction mixture [1 mg/ml 5 4-chloro-5-bromo-3-indolyl- $\beta$ -galactoside, 4mM K<sub>4</sub>Fe(CN)<sub>6</sub> x 3H<sub>2</sub>O, 2mM MgCl<sub>2</sub> in PBS] at 30°C for 1 to 2 days. Then, samples were washed in PBS for 5 hours and transferred to 30% sucrose for storage.

10 Samples were then embedded in Tissue Tek (Miles, USA) and 15  $\mu$ m sections were cut on silane-treated slides. Sections were post-fixed in 4% paraformaldehyde for 5 minutes, and washed twice in PBS and once in distilled water. Nuclear fast red was applied as a counterstain.

15 Results are provided in Figures 5 and 6. Figures 5A-5D show expression of the mouse Tie promoter in 9.5 (Figures 5A and 5B) and 11.5 (Figures 5C and 5D) day post coitum mouse embryos. As seen in the figures, activity of the 20  $\beta$ -galactosidase reporter gene is found in the developing heart (h), branchial vessels (ba), paired dorsal aorta (da), vitelline artery (v), umbilical artery (u), and in capillaries (c) of 9.5 day post coitum embryos. Two days later (figures 5C and 5D), 25 a similar pattern is found with the addition of staining in the mesonephros (m) and the veins of the liver(l).

Figures 6A through 6F show Tie promoter activity in 9.5, 11.5, and 13.5 day post coitum 30 embryos. All endothelial cells of the cardiac region are stained, indicating expression under control of the promoter. Staining is observed in lung, but the bronchi are negative. Brain tissue of 15.5 day embryos also shows staining. Figure 6D 35 shows that the promoter is expressed in veins of the

- 17 -

liver and Figure 6E shows staining in the developing bone trabeculae. The developing cortex of the kidney shows staining, expression being most prominent in the glomeruli.

5 To study the promoter activity during development, the 0.73mpromSDK-LacZ and 5.0mpromSDK-LacZ DNAs were injected into fertilized mouse oocytes. Six transgenic mice were obtained, transgenic males were mated with wild-type NMRI 10 females and the offspring (86 for 735 bp fragment and 57 for 5.0 kb fragment) were analyzed on days 7.5 - 17.5 of development. Of the F1 offspring, 40% were positive in LacZ staining, although the embryos showed a variation of the intensity of the reaction 15 color. No staining was seen in 7.5 day post-coital embryos, whereas in 8.5 day post coitum embryos, endothelial cells of the dorsal aorta and forming heart were strongly positive. Certain cells of the head mesenchyme, presumably differentiating 20 angioblasts, showed a faint signal, and the extraembryonic tissues, such as allantois and yolk sac, contained positive vessels.

The complexity of the vascular system increases rapidly in the developing embryo, and in 25 9.5 day post coitum embryos promoter activity was seen in the above mentioned vessels as well as in the intersomitic arteries. An especially intense staining was seen in the developing ventricles of the heart. In 11.5 day post coital embryos the 30 capillary system is well-developed and therefore the staining associated with large vessels of the embryo and the endocardium was only faintly discerned through the dense network of blue-stained capillaries. The details of vascular system were 35 better visualized in high magnification of tissues

- 18 -

of day 11.5 and 15.5 post coital embryos. That staining pattern corresponds to the expression pattern obtained in *in situ* hybridization. As shown in Figures 4A and 4B, the endocardium of the 5 heart, the veins and the arteries of the head mesenchyme showed LacZ signal. No significant differences were seen in the staining patterns obtained with mouse 753 bp and human 5.0 kb promoter fragments.

10 In order to determine if the promoter activity of the 735 bp mouse fragment correlates with expression of Tie mRNA in adult tissues, various tissue types obtained from 8-week old transgenic mice were stained for  $\beta$ -galactosidase 15 activity. As shown in Figures 7A and 7B, intense staining was observed in lung (figure 7A) and bone marrow (designated bm in Figure 7B). Figure 7B also shows staining in capillaries associated with hair follicles (designated by the arrow in Figure 7B). 20 Slightly less staining was observed in kidney glomeruli (Figure 7C, designated "g") and vessels surrounding the tubuli (Figure 7C, designated by the arrowhead). Figure 7D shows staining in the endocardium. Neither large hepatic vessels (v in 25 Figure 7E) or sinusoidal capillaries (not shown) stained with LacZ in adult mice. However, small vessels surrounding the veins did stain [Arrows in Figure 7(E)]. As shown in Figure 7(F), interstitial capillaries of the brain were stained [Arrowheads 30 in Figure 7(F)]. Similar results were obtained when transgenic mice expressed the 5 kb human Tie promoter.

The present invention has been described in terms of its preferred embodiments. Accordingly, 35 the invention should be limited only by the scope of the appended claims.

CLAIMS

What is claimed is:

1. A promoter for a mouse Tie receptor tyrosine kinase, said promoter comprising the nucleic acid sequence shown in SEQ. ID. NO: 1.
2. A portion of the promoter according to claim 1; wherein said portion is capable of promoting expression of an endothelial cell receptor tyrosine kinase.
3. A promoter for a human Tie receptor tyrosine kinase, said promoter comprising the nucleic acid sequence shown in SEQ. ID. NO: 2.
4. A portion of the promoter according to claim 3; wherein said portion is capable of promoting expression of an endothelial cell receptor tyrosine kinase.
5. A vector comprising the promoter according to claim 1.
6. A vector comprising the promoter according to claim 2.
7. A host cell comprising the vector according to claim 3.
8. A host cell comprising the vector according to claim 4.
9. A host cell comprising the vector according to claim 5.
